We propose the new approach for taking into account the Q^2 dependence of measured asymmetry A_1 . This approach is based on the similarity of the Q^2 behaviour and the shape of the spin-dependent structure function $g_1(x, Q^2)$ and spin averaged structure function $F_3(x, Q^2)$. The analysis is applied on the SMC and E154 experimental data.

An experimental study of the nucleon spin structure is realized by measuring of the asymmetry $A_1(x, Q^2) = g_1(x, Q^2)/F_1(x, Q^2)$. The most known theoretical predictions on spin dependent structure function $g_1(x, Q^2)$ of the nucleon were done by Bjorken¹ and Ellis and Jaffe² for the so called *first moment value* $\Gamma_1 = \int_0^1 g_1(x) dx$.

Studying the properties of $g_1(x, Q^2)$ and the calculation of the Γ_1 value require the knowledge of structure function g_1 at the same Q^2 in the whole x range. Experimentally asymmetry A_1 is measuring at different values of Q^2 for different x bins. An accuracy of the modern experiments^{3,4,5,6} allows to analyze data in the assumption⁷ that asymmetry $A_1(x, Q^2)$ is Q^2 independent (structure functions g_1 and F_1 have the same Q^2 dependence)

$$A_1(x, Q^2) = A_1(x) \quad (1)$$

But the precise checking of the Bjorken and Ellis - Jaffe sum rules requires considering the Q^2 dependence of A_1 or g_1 . Moreover, the assumption (1) the asymmetry $A_1(x, Q^2)$ is Q^2 independent does not follow from the theory. On the contrary, the behaviour of F_1 and g_1 as a functions of Q^2 is expected to be different due to the difference between polarized and unpolarized splitting functions.

There are several approaches (see^{8,9} and its references) how to take into account the Q^2 dependence of A_1 . They are based on different approximate solutions of the DGLAP equations. Some of them have been used already by Spin Muon Collaboration (SMC) and E154 Collaboration in the last analyses of experimental data (see⁴ and⁶, respectively).

In this article we suggest to use another idea which is based on the observation that the splitting functions of the DGLAP equations for the SF g_1 and F_3 and the shapes of the SF themselves are the similar in a wide x range and, thus, the Q^2 dependence of them has to be close as a consequence. Our approach for Q^2 -dependence of A_1 are very simple (see eq.(2)) and leads to the results, which are very similar to ones based on the DGLAP evolution. To demonstrate the validity of the observation, we note that the r.h.s. of DGLAP equations for NS parts of g_1 and F_3 is the same (at least in first two orders of the perturbative QCD) and differs from F_1 already in the first subleading order. For the singlet part of g_1 and for F_3 the difference between perturbatively calculated splitting functions is also negligible (see ^{13,15}). This observation allows us to conclude the function

$$A_1^*(x) = \frac{g_1(x, Q^2)}{F_3(x, Q^2)}$$

should be practically Q^2 independent and the asymmetry A_1 at some Q^2 can be defined than as :

$$A_1(x_i, Q^2) = \frac{F_3(x_i, Q^2)}{F_3(x_i, Q_i^2)} \cdot \frac{F_1(x_i, Q_i^2)}{F_1(x_i, Q^2)} \cdot A_1(x_i, Q_i^2), \quad (2)$$

where x_i (Q_i^2) means an experimentally measured value of x (Q^2).

To apply the proposed approach we use the SMC ⁴ and E154 Collaboration ^{5,6} data. To use relation (2) we parametrize CCFR data on $F_2(x, Q^2)$ and $xF_3(x, Q^2)$ ¹⁰ in the same form as NMC fit of the structure function $F_2(x, Q^2)$ ¹¹ (see ¹⁵). To obtain structure function $F_1(x, Q^2)$ we also take the parametrization of the CCFR data on $F_2(x, Q^2)$ ¹⁰ and the SLAC parametrization of $R(x, Q^2)$ ¹² and use relation :

$$F_1(x, Q^2) = \frac{F_2(x, Q^2)}{2x(1 + R(x, Q^2))} \cdot \left(1 + \frac{4M^2x^2}{Q^2}\right), \quad (3)$$

We use in Eq.(2) parametrizations of CCFR data ¹⁰ for both SF $xF_3(x, Q^2)$ and $F_2(x, Q^2)$ to avoid systematical uncertainties and nucleon correlation in nuclei.

The SF $g_1(x, Q^2)$ is calculated using the asymmetry $A_1(Q^2)$ as

$$g_1(x, Q^2) = A_1(x, Q^2) \cdot F_1(x, Q^2), \quad (4)$$

where spin average SF F_1 has been calculated using NMC parametrization of $F_2(x, Q^2)$ ¹¹. The results are presented in Fig. 1 and Fig. 2 for E154 and

SMC data, respectively. Our results are in an excellent agreement with the calculations which are based on direct DGLAP evolution.

Figure 1. The structure function $xg_1^n(x, Q^2)$ evolved to $Q^2 = 5\text{GeV}^2$ using our eq.(2), DGLAP NLO evolution and the assumption that g_1^n/F_1^n is Q^2 independent. Last two sets are from⁶.

Figure 2. The structure function $xg_1^n(x, Q^2)$ evolved to $Q^2 = 10\text{GeV}^2$ using our eq.(2), the assumption that g_1^n/F_1^n is Q^2 independent, and DGLAP NLO evolution according to the analysis⁹.

To make another comparison with the theory we have calculated also the first moment value of the structure function g_1 at different Q^2 . Using eq.(2), we recalculate the SMC measured asymmetry of the proton and deuteron and E154 one of neutron at $Q^2 = 100\text{ GeV}^2$, 30 GeV^2 , $Q^2 = 10\text{ GeV}^2$ and 3 GeV^2

Table 1: The mean values of $\Gamma_1^p - \Gamma_1^n$.

Q^2 (GeV ²)	100	30	10	3
SMC proton and deuteron data				
A_1 -scaling	0.297	0.226	0.202	0.170
Evolution			0.183	
A_1^* -scaling	0.210	0.201	0.191	0.176
SMC proton and E154 neutron data				
A_1 -scaling	0.221	0.209	0.194	0.170
A_1^* -scaling	0.194	0.190	0.185	0.175
Theory	0.194	0.191	0.187	0.180

and get the value of $\int g_1(x)dx$ through the measured x ranges. To obtain the first moment values $\Gamma_1^{p(d)}$ we use an original estimations of SMC and E154 for unmeasured regions. As the last step we calculate the difference $\Gamma_1^p - \Gamma_1^n$ (for SMC proton and deuteron data $\Gamma_1^p - \Gamma_1^n = 2\Gamma_1^p - 2\Gamma_1^d/(1 - 1.5 \cdot \omega_D)$ where $\omega_D = 0.05$). In Table 1 we present the results for the mean values of $\Gamma_1^p - \Gamma_1^n$, because the errors coincide with the errors of original analyses^{4,5,6a}. The value of $\Gamma_1^p - \Gamma_1^n$ at $Q^2 = 10 \text{ GeV}^2$ obtained by direct DGLAP evolution are taken from article⁴.

Let us now present the main results, which are following from the Table 1 and the Figures.

- The results are in excelent agreement with $g_1(x, Q^2)$ data of SMC and E154 Collaborations, based on direct DGLAP evolution.
- Our method allows to test of the Bjorken sum rule in a simple way with a good accuracy. Obtained results on the $\Gamma_1^p - \Gamma_1^n$ show that used experimental data well confirm the Bjorken sum rule prediction.

Acknowledgments

One of us (AVK) is gratefull very much to Organizing Committee of Workshop DIS98 for the financial suppor.

^aThe theoretical predictions computed in¹⁴ to the third order in the QCD α_s .
